Validation: the Hoelder bound $|B(x)| \le M(x)\cdot\delta(x)$ (Prop. 6.2.2), checked on a case with Z observed

Orange: true bias $B(x)=\mu(x)-\mu_{obs}(x)$ (both objects fully computable here since ρ_{XZ}, ρ_{YZ} are known). Blue band: ± the theorem's bound, using the CORRECTED $\delta(x)$ [quadrature] and $M(x)=1$ [Prop. 5.4.2]. The bound holds everywhere, as it must — but note how much slack there is: the actual bias uses only ~2–10% of the ceiling the theorem allows for.
