

## Same bound, calibrated to Kendall's $\tau$ (Gaussian X-Z copula, exact map)

x-axis recalibrated via  $\tau \rightarrow \rho = \sin(\pi\tau/2) \rightarrow \delta(x, \rho)$  (numerical quadrature, not the broken closed form). Dotted line:  $\tau(X, Y)$ , i.e. a confounder as strongly associated with X as Y itself already is — a natural, estimable benchmark.

$M(x) \cdot \delta(x)$   
(bound on  $|B(x)|$ )
