

Ignorance Ratio: $IR(x; d_max) = \text{width}(\text{sensitivity}) / \text{width}(\text{oracle})$

IR = 1 iff the researcher knows d_true exactly.
IR is monotone decreasing in d_max : less knowledge $\rightarrow$ wider interval.
Note Gaussian cases: IR spikes at extreme x due to small oracle width.

Knowledge-Gain Function: width reduction from complete ignorance toward oracle

$KG(x; d_max) = 1 - \text{width}(d_max) / \text{width}(d_max = 0.20)$
 $KG = 0$ at $d_max = 0.20$ (baseline ignorance); $KG = 1$ when $d_max = d_true$ (oracle).
