

Same bound, calibrated to Kendall's τ (Gaussian X–Z copula, exact map)

x-axis recalibrated via $\tau \rightarrow \rho = \sin(\pi\tau/2) \rightarrow \delta(x, \rho)$. Dotted line: $\tau(X, Y)$, i.e. a confounder as strongly associated with X as Y itself already is — a natural, estimable benchmark.

$M(x) \cdot \delta(x)$
(bound on $|B(x)|$)
